Special Topics

Samasoni Sauni, Regional Programme Coordinator

Regional guidelines - Spatial Prioritization modelling
RSTC Virtual Meeting 19th 20th October, 2020
Session 5: Special Topics

1. Reflect on the (modified) approved R2R Science-Policy theory of change adapting to changing circumstances, and provide renewed commitments, if any, towards mainstreaming R2R in either planning process and/or policy development;

2. Reflect on the importance of R2R approach in natural resource management and governance, and the utility of land-sea modelling as a decision support tool and endorse the regional guidelines;

3. Discuss and appreciate the importance of available-accessible data and information sharing, including through the newly developed (and soon to launch) the “Pacific State of Coast Spatial Data Infrastructure for the Pacific Ridge to Reef Programme.”
• Regional guidelines for implementing the R2R conceptual procedural framework for the identification and spatial prioritization of conservation land/sea area

**RATIONALE**

**SCOPE**

**BACKGROUND**

• Delevaux et al. 2018
What’s spatial prioritization modelling?

Science-based and spatial planning procedure that supports selection of priority areas and sites for R2R interventions and reforms.

It demonstrates the interface between science and policy thereby improving the understanding, and enriching the knowledge base on the cause and effect relationship of “whole-of-island” environmental degradation. It also develops systems to better manage the impacts.
National scale approach:
Adapt & apply a spatially-explicit framework with scenario planning to identify national priority areas that benefit land & sea

Local scale approach:
Downscale this framework to test the effect of proposed local R2R management actions in one priority watershed
Specific Tasks

• **Water Catchment Areas, High Islands**
  Evaluate where land-use change and habitat scenarios would impact sediment runoff and downstream coral reefs to identify priority areas on land where conservation restoration could promote coral reef resilience in the face of climate change.

• **Building the R2R land-sea modelling framework** requires inputs of broad range of satellite and empirical data to make it work.
Process, Outputs

- The procedure incorporates quantifiable criteria and indicators for the identification of priority R2R sites.
- The procedure reflects the importance of sites from the lenses of biological, environmental, and socio-economic conditions nationally.
- The procedure will cover the following:
  1. Existing data and defined criteria, identify national level priority sites or target areas.
  2. Results will be used to support national planning for ICM and IWRM.
  3. Information generated from a land-sea model at a demonstration site will highlight those areas within the overall identified priority area that are most critical to protect.
Stepwise procedures

- Participatory **planning** processes
- Develop potential future land-use or marine-use change **scenarios**
- Identify relevant **spatial data gaps** important for analyses and inputs into land-sea **models**
  - If yes, then prepare to carry out field work to ground-truth & collect additional primary data
- Prepare sampling protocols & designs for **field work**
• Coordinate logistical arrangements including teams of people involved and their roles.
• Carry out field work closely adhering to sampling design and following deadlines and details set out in the implementation plan.
• Data processing and analyses
• Additional survey work to optimise calibration of marine and terrestrial models. The exercise should be participatory to promote capacity building.
Calibrate coral reef models

Benthic models = sediment + habitat

Fish models = sediment + habitat + \textit{benthic} indicators
Scenario analysis

1. Predict coral reef benthic & fish indicators under present & each scenario

2. Calculate the coral reef indicators change for each scenario compared to present
1. Model the sediment export & plume under present & each deforestation scenario

2. Identify coral reef areas exposed to significant change in sediment for each scenario compared to present

3. Identify the watersheds supplying the most sediment (>40%) to those coral reef areas
Spatial prioritization

1. Characterize the **potential marine impact** using **coral % cover & fish biomass** from **empirical data**

2. Prioritize **watersheds** by **potential marine impact**

3. Identify **land areas** exposed to **significant change in sediment export** under **each scenario** compared to **present**
• Prepare technical reports that include clearly the methods employed, model outputs, maps depicting priority areas and sites, and packaged models.

• Present and discuss methods and outputs with other actors or peer review and refinement.
LOCAL-SCALE APPROACH RESULTS
Present scenario

8% of Human LUC

1,260 ton/yr
9.7 ton/km²/yr

69% of Native forest

760 ton/yr
50%

22% of Grass/shrubland
Calibrated coral reef models

Relationships:
- Positive
- Negative
- Concave or Convex
Marine closure scenario

Closed area

Fish biomass +2.5 tons
Restoration scenario

+1,330 ha of Native forest

- 210 ton/yr
Restoration scenario

+Marine closure

<table>

<tr>
<td>-1.5% macroalgae</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Urbanization scenario

+ 1,340 ha of Human LUC

+ 5,180 t/yr
Urbanization scenario

Habitat quality
75 ha
-7% coral
+2% macroalgae

Fish biomass
-6.7 tons

Fish biomass
-5 tons

+Marine closure
Benefits & Implications

- Use existing data to define criteria and identify national level priority sites or target areas - diagnostic analysis stakeholder workshops or simply reporting back to communities in targeted demonstration project sites.
- Use the results to support future upscaling R2R investments and national planning for ICM.
Benefits of R2R approach

Restore native forest: +1,330 ha

-210 ton/yr of sediment

Restore/protection marine habitat: Up to 75 ha

Restore/protection fish biomass: Up to 8.3 ton

+ marine closure

+ no more urbanization
Collaborative management

1. Provide **information** to foster **dialogue** between decision-makers

2. Can be applied as part of an **iterative** decision-making process

*Diagram:

- Define problem
- Conservation planning
- Scenario analysis
- Scenario design
- Model development
Support decision making

1. Prioritize **conservation areas** at the **national-scale** that can **benefit** both **terrestrial** & **marine** environments

2. Support **local** decision-making by testing **policy actions** & estimating potential **outcomes** prior implementation
Key Challenges

- Spatial data & data gaps for land-sea modelling
- SPC GEM spatial datasets
- Freely available software packages (InVEST SDR & R)
- Open access QGIS
Decision support tool in data poor regions

• Resolution of input foundational layers (soils, currents)

• Decision support tool relies on static modelling
  – R2R framework can give an idea where may degrade or recover but not a dynamic model where possible to see impacts through measuring indicators

• Suggested approach to address challenges (para. 33)
(i) Reflect on the design, clarity and relevance of the R2R spatial prioritization and planning procedures noting the outcomes of its trials in Vanuatu; and

(ii) **Discuss and approve** the practical application of the guidelines to implement the spatial prioritization and planning procedures to identify conservation areas in future upscaling R2R investments and ICM planning in PICs.
• Thank you...
